Control method: Fumigation of rabbit warrens with chloropicrin

Assumptions: This is not considered an acceptable method therefore there is no standard operating procedure.

PART A: assessment of overall welfare impact

DOMAIN 1 Water or food restriction, malnutrition
- No impact
- Mild impact
- Moderate impact
- Severe impact
- Extreme impact

DOMAIN 2 Environmental challenge
- No impact
- Mild impact
- Moderate impact
- Severe impact
- Extreme impact

DOMAIN 3 Disease, injury, functional impairment
- No impact
- Mild impact
- Moderate impact
- Severe impact
- Extreme impact

DOMAIN 4 Behavioural or interactive restriction
- No impact
- Mild impact
- Moderate impact
- Severe impact
- Extreme impact

DOMAIN 5 Anxiety, fear, pain, distress, thirst, hunger
- No impact
- Mild impact
- Moderate impact
- Severe impact
- Extreme impact

DURATION OF IMPACT
- Immediate to seconds
- Minutes
- Hours
- Days
- Weeks

Overall impact: Mild
Control method: Fumigation of rabbit warrens with chloropicrin

Assessment performed by: Humaneness Assessment Panel
Date of assessment: 15-16 October 2009
Date file created: 3/05/2011
Last saved 3/05/2011 1:34 PM

PART A: assessment of risk

<table>
<thead>
<tr>

<td>1</td>
<td>No impact in this domain.</td>
</tr>
<tr>
<td>2</td>
<td>No impact in this domain.</td>
</tr>
<tr>
<td>3</td>
<td>No impact in this domain.</td>
</tr>
<tr>
<td>4</td>
<td>Prior to fumigation, rabbits are driven underground into the warren by making loud noises (e.g. riding motorbikes) and using dogs. These disturbances are likely to cause 'flight or fight' stress responses that are similar to those activated when prey flee from predators. These endocrine responses are short lived and stress hormone levels quickly return to normal. Rabbits react to fumigation by confining themselves to parts of the warren farthest from entrances, attempting to dig out of the warren at a blocked entrance, making a new exit where a burrow passes close to the surface or moving around the warren system in a disturbed state.</td>
</tr>
<tr>
<td>5</td>
<td>Within a few minutes of encounter with the gas, rabbits appear to be immediately irritated (rapid blinking and nose twitching) and display periodic bursts of flight. This is followed by immobilisation in a hunched posture and distress vocalisation, which can be indicative of pain.</td>
</tr>

| SCORE FOR PART A: | 3 |

Summary of evidence:

Time to insensibility (minus any lag time)

Time to death (TTD) is 70-95 minutes when power fumigation is used (peak chloropicrin concentration 11.7-97.7 ppm). There can be wide variation in time to death that is related to exposure (e.g. from diffusion fumigation LD₅₀ 14-71 ppm, TTD 15-135 minutes; LD₅₀ 744 ppm, TTD 5 minutes; LD₅₀ 1086 ppm, TTD 15 minutes). Exposure to chloropicrin that is not acutely lethal may cause a protracted death over hours of days.
Suffering – Toxocosis includes severe upper respiratory tract irritation. Initial signs of toxocosis include rapid blinking, nose twitching, distress vocalisations and laboured breathing\(^7\). Signs prior to collapse include profuse lacrimal (eye and tear duct) and nasal discharge, congested breathing and uncoordinated paddling\(^7\). Signs before death are variable with some rabbits remaining hunched and immobile for up to an hour before death\(^6\).

Human cases of chloropicrin poisoning include symptoms such as eye and upper respiratory tract infection, lacrimation, stomach upset, vomiting, nausea, coughing and headache\(^8\). After exposure to a sublethal dose some symptoms may persist for up to 11 days\(^9\).

Rabbits that escape from warrens after fumigation may die up to a week after acute sublethal exposure\(^6\).

Summary

</table>

Comments

Lethal toxocosis from chloropicrin fumigation causes death by pulmonary oedema, bronchopneumonia or bronchiolitis obliterans\(^10\).

Pain may be expressed as a change from normal behaviours. Clinical signs associated with pain include hunched posture and remaining immobile\(^5\).
